

Battery Breakdown

**Why are e-scooter and e-bike
batteries exploding in people's homes
and what can be done about it?**

**A report into the increase in lithium-ion battery fires
and recommendations for addressing the problem**

E-bike and e-scooter fires pose a significant risk due to their use of lithium-ion batteries. A fully charged e-bike battery contains a similar amount of energy to six hand grenades. When a battery fails this can lead to thermal runaway. Thermal runaway causes a prolonged release of energy, resembling an uncontrollable explosive firework and results in fires with temperatures exceeding 600 degrees Celsius, which spread rapidly, release toxic gases and are almost impossible to control.

Our Asks

Electrical Safety First asks the Welsh Government to pursue a public awareness campaign, to ensure that the public is adequately educated on the risks from lithium-ion batteries, and how to safely handle the products which use them.

We also ask that the Welsh Government expand its current requirements around fire data collection, to enable the categorisation of fires specifically to the lithium-ion batteries used in electric micromobility devices.

Summary

Concerns are mounting over the risks to personal health and property posed by electrified micromobility (e-micromobility) such as e-bikes and e-scooters. Since the start of 2023 fires from the lithium-ion batteries used to power these devices have been linked to eight deaths in the UK, and left others hospitalised or seriously injured, with significant damage also to property.

The growing popularity of e-micromobility – with Mintel estimates placing the market value of e-bikes at £300 million in 2022, and double-digit volume growth forecasted for 2024 onwards – means that, unless action is taken, these risks will continue to grow.

The increasing number of fatalities, injuries and fires caused by malfunctioning e-bikes and e-scooters is a grave matter of concern, not just within Wales, but across the globe. However, due to the potential benefits of e-micromobility compared to traditional transport – fewer emissions and lower cost – their popularity is expected to grow.

The potential for popularised e-micromobility is especially poignant for Wales in light of the *Active Travel Act 2013*, which led to the introduction of pilot schemes for e-bikes as an economical and green form of travel for individuals and businesses.

While this initiative holds considerable potential for the environment, it does merit special consideration of the challenges from growing numbers of e-bikes and e-scooters, and the role that data may hold in future-proofing such travel strategies that encourage e-micromobility use.

It is vital to ensure that the public is adequately educated on the risks from lithium-ion batteries, and how to safely handle e-micromobility products. This is especially so in Wales, considering the official encouragement of e-bikes as a viable form of alternative travel. Regrettably, just this week, a fire in Torfaen was caused by an e-scooter battery on charge.

Unfortunately, regional fire data collection practices vary considerably, with different levels of detail and types of information being recorded. If we are to ensure the safety of consumers as the popularity of e-micromobility transport grows, it is imperative that fire data collection practices are improved to accommodate the growing risks from lithium-ion batteries.

Enhanced data collection practices, particularly for fire and rescue data, would provide legislators with information on which to base future policy positions, and facilitate targeted intervention where necessary if locational data of fires is collected.

We therefore call upon the Welsh Government to mitigate the risks from e-micromobility products by pursuing a consumer awareness campaign to ensure that the public is adequately educated on best practice when handling these products, and to improve fire data collection practices to include specific references to lithium-ion batteries.
